其重要ナ ル要處 ヲ

XVIII.—OF THE OVULE.

526. The Ovule 190 is a body borne by the placenta (486), and destined to become a seed.

527. It is to the carpel (480) what marginal buds are to leaves (293), and to the central placenta what buds are to branches.

528. It may be regarded as a bud with a retrograde development.

529. The ovule is usually inclosed within an ovary (472); but in Conifers and Cycads it is destitute of any covering, and is exposed, naked, to the influence of the pollen.

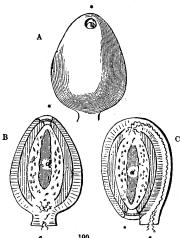

530. It is either sessile, or attached by a little stalk called the *funiculus*, or *podosperm*. The point of union of the funiculus and ovule is the *base* of the latter, and the opposite extremity is its apex.

531. It consists of a sac, or of two sacs, one inclosed within the other, and of a nucleus within the sacs.

But M. Planchon has shown that the nucleus of Veronica hederæfolia is destitute of sacs, being absolutely naked. See his excellent *Mémoire sur les vrais et les faux arilles*. 4to, Montpellier, 1844.

532. These sacs are called the primine and secundine.

The nucleus is first formed, then the secundine, and then the primine, as is shown by the figures at fig. 180. The nucleus would seem to be itself a grow-

ing point, and the sacs to be scales formed round it analogous to the scales of a leaf-bud. In the bud itself the growing point comes first, necessarily; then succeed the scales.

533. The primine, secundine, and nucleus, are all connected with each other by a perfect continuity of tissue, at some point of their surface.

534. When the parts of the ovule undergono alteration of position during their growth, the two sacs and the nucleus are all connected at the base (530) of the ovule, which is orthotropal or atropal 190 a 191 a.

535. And then the base of the nucleus and that of the ovule are in immediate connection with each other 1773.

536. But the relative position of the sacs and the base of the ovule are often entirely altered during the growth

of the latter, so that it frequently happens that the point of union of the sacs and the nucleus is at the apex (530) of the ovule 190 c.

537. And then the base of the nucleus is at the apex of the ovule.

538. In such cases, a vascular connection is maintained between the base

95

THE OVULE.

of the ovule and the base of the nucleus, by means of a bundle of vessels called a $raphe^{190}$.

539. The normal position of this raphe is on the side of the ovule, next

the placenta.

540. The expansion of the raphe, where it communicates with the base of the nucleus, gives rise to the part of the seed called the chalaza (642) 190 f.

541. When the ovule is curved downwards so as to approach the placenta,

it is camptotropal ^{191 b}; when curved downwards and grown to the lower half, anatro¹ pal ^{190 c 191 c}; when attached by its middle
so that the foramen is at one end and the
base at the other, it is campylotropal or
amphitropal ^{191 c}; when horse-shoe shaped
it is lycotropal ^{191 f}; when anatropal with
the raphe half loose, it is semianatropal ^{191 d}.

542. The mouths of the primine and secundine usually contract into a small

aperture called the foramen of the ovule, or the exostome 190 *.

543. The apex of the nucleus is always applied to this foramen.

544. In consequence of the relation the base of the nucleus bears to the base of the ovule, the foramen will be at the apex of the ovule when the two bases correspond, and at the base of the ovule when the two bases are diametrically opposite.

545. The foramen indicates the future position of the radicle of the embryo; the radicle being usually next the foramen. This is a fact of

great importance in practical Botany.

Gasparrini, however, asserts that, in the China orange, this is sometimes reversed: the radicle being turned to the chalaza.

546. Within the nucleus is a cavity or bag, called the sac of the amnios 190 dd, containing a fluid, in which the embryo is developed.

The nucleus of some plants is pierced by the amniotic sac, which projects beyond the foramen as a tube, as in Santalum, Narthecium (557), &c. M. Planchon also found that in Veronica hederæfolia (531) the side of the naked nucleus is ruptured lengthwise by the amniotic sac, so as to become naked also. Something quite analogous occurs in Avicennia.

HYBRIDS.

XIX.—OF FERTILISATION.

547. THE fertilisation of a flower appears to be accomplished by the action of pollen (452) upon the stigma (477).

The proofs of this are so many and so seemingly conclusive, that it is usual to regard the proposition as unassailable. But it is necessary to add that some facts are apparently irreconcilable with it. The chief of these is the case of a directions Spurgewort, allied to Sapium, and called Coelebogyne, of which the female only is known. This plant produces ripe and perfect seeds in the Botanic Garden, Kew; and yet the most diligent search has failed to discover any polliniferous flowers. Is it fertilised by the pollen of some other plant? This seems improbable, because the seedlings are exactly like their mother, which is not the case with vegetable hybrids (551). Certain experiments instituted by M. Girou de Buzareingues have led him to the conclusion, that in Hemp, the Lychnis dioica, and other dioccious plants, the presence of pollen is not necessary to fertilise the ovule (Ann. Sc., 1st ser., xxx. 406). And it appears certain that in some instances Cucumbers have swelled fruit, and ripened seeds, in the absence of pollen. Finally, we have the assurance of Decaisne that in Viscum the ovule is not formed till six weeks or two months after the pollen has acted on the stigma; and Professor Gasparrini maintains that in the Fig-tree the embryo is formed without any fertilisation whatever; for the summer crop of this fruit is obtained from female flowers, which can by no possibility communicate with stamens, the male flowers not being produced at that time, and nevertheless it abounds in seeds containing the embryo; while, on the other hand, the spring figs, in which male flowers do occur, never have any embryo in their seeds! The female Hop is fertile without a male. (See Ann. Sc., 3rd ser., v. 306.)

548. The result of that action seems to be the formation of an embryo (650) within the nucleus of the ovule.

549. When the pollen and stigma each belong to the same species, then that species is propagated without material alteration.

550. But if they belong to different species, then their mutual action results in the production of hybrids, or vegetable mules.

This is not an artificial process, but happens frequently in wild nature. and is yearly giving rise to the false species of botanists.

551. A hybrid is not necessarily sterile, but is often capable of propagating its race.

552. It is usual for the hybrid to resemble the male parent most in foliage, and the female in flower.

This has been proved to be the general rule by the numerous experiments of the Dean of Manchester. See Dr. Herbert's papers in the second volume of the Journal of the Horticultural Society.

553. The expulsion of pollen from the anther is due to the contraction of its valves. It is naturally effected in dry, warm weather; and cannot take place in the presence of wet, except in species whose fertilisation is effected under water.

It is not improbable that, as De Buzareingues has suggested, the noxious effect of wet upon fertilisation may consist partly in preventing the anther-cells from opening, and partly in the activity which it gives to the vegetation of the

POLLEN-TUBES.

554. The pollen is enabled to act upon the ovule by means of an extension of its inner lining, if it has more than one coat (454), in the form of a

555. The pollen-tube insinuates itself between the cells of the stigma 192, and passes down its conducting tissue till it reaches the interior of the

556. Having reached the interior, a similar tube appears, and connects the apex of the nucleus of the ovule, through the foramen, with the conducting tissue of the style 193 194.

557. The result of this action is the formation of a living point which

eventually becomes the embryo.

In the present state of knowledge as to this point, the above seems to be the safest way of stating facts. The common opinion among botanists is, that the pollentubes pass directly to the nucleus, through the foramen. There is no question that pollen-tubes of great length grow out of the pollen-grains, and plunge into the stigma. The curious phenomena connected with Asclepiads, and more especially with Morrenia, in which great mechanical difficulties are overcome by the pollen-tubes before they can reach the stigma, prove that this phenomenon is connected with vitality of a very high order. Neither is there room for doubting whether similar tubes appear in the cavity of the ovary, connecting the conducting tissue of the style with the apertures of the ovules (see figs. 193 and 194).

97

But it may be reasonably questioned whether the tubes are the same in both cases. Not that there is any difficulty in understanding how so great and rapid a growth on the part of the pollen-tubes as is assumed should take place; for the starch of the fovilla (453) may be regarded as a store of organizable matter provided for this express purpose, as Brown suggested. The doubt arises from the impossibility in many cases of so tracing the small delicate transparent threads as to be certain that they do not become blended with long cells having a different origin, and that it is not the latter which are seen in the cavity of the ovary, It is asserted, indeed, that these tubes have been distinctly traced ab origine; and no doubt can be entertained that observers have thought so. The question is, may they not have been deceived? Dr. Dickie positively asserts that in Narthecium the so-called pollen-tubes in the interior of the ovary are really ovule-tubes, or delicate filaments, rising from the apex of the nucleus, and ad-

placenta.—Schleiden.

Fig. 192.—A grain of pollen sending its pollen-tube down among the stigmatic cells of Papaver.—Mohl. Fig. 193.—A longitudinal section of the carpel of Euphorbia pallida at the time when the pollen-tube p has reached the apex of the nucleus n. It appears as a dark streak passing through the filamentary conducting tissue of the style; a is the sac of the amnios, and c the chalaza.—Schleiden. Fig. 194.—A longitudinal section of the interior of the ovary of a Heliamthemum, with the pollen-tubes descending from a, and reaching the foramina of the ovules which are forcibly detached from their Negerita.—Schleiden.
